#### Softmax Classifier

This exercise guides you through the process of classifying images using a Softmax classifier. As part of this you will:

- · Implement a fully vectorized loss function for the Softmax classifier
- · Calculate the analytical gradient using vectorized code
- · Tune hyperparameters on a validation set
- Optimize the loss function with Stochastic Gradient Descent (SGD)
- · Visualize the learned weights

```
In [1]: # start-up code!
            import random
            import matplotlib.pyplot as plt
            import numpy as np
            %matplotlib inline
            plt.rcParams['figure.figsize'] = (10.0, 8.0) # set default size of plots
            plt.rcParams['image.interpolation'] = 'nearest'
plt.rcParams['image.interpolation'] = 'nearest'
            plt.rcParams['image.cmap'] = 'gray
            # for auto-reloading extenrnal modules

### Implementing a Neural Network

%reload\_ext autoreload

In this exercise we will develop a neural network with fully-connected layers to perform classification, and test it out on the CIFAR-10 dataset.

```
In [83]: # A bit of setup
import numpy as np
import matplotlib.pyplot as plt

%matplotlib inline
plt.rcParams['figure.figsize'] = (10.0, 8.0) # set default size of plots
plt.rcParams['image.interpolation'] = 'nearest'
plt.rcParams['image.cmap'] = 'gray'

# for auto-reloading external modules
# see http://stackoverflow.com/questions/1907993/autoreload-of-modules-in-ipython
%load_ext autoreload
%autoreload 2

def rel_error(x, y):
    """ returns relative error """
    return np.max(np.abs(x - y) / (np.maximum(le-8, np.abs(x) + np.abs(y))))
The autoreload extension is already loaded. To reload it, use:
```

The neural network parameters will be stored in a dictionary ( mode1 below), where the keys are the parameter names and the values are numpy arrays. Below, we initialize toy data and a toy model that we will use to verify your implementations.

```
In [84]: # Create some toy data to check your implementations
         input size = 4
         hidden size = 10
         num_classes = 3
         num_inputs = 5
         def init toy model():
             model = {}
             model['W1'] = np.linspace(-0.2, 0.6, num=input size*hidden size).reshape(input size, hidden size)
             model['b1'] = np.linspace(-0.3, 0.7, num=hidden_size)
             model['W2'] = np.linspace(-0.4, 0.1, num=hidden_size*num_classes).reshape(hidden_size, num_classes)
             model['b2'] = np.linspace(-0.5, 0.9, num=num_classes)
             return model
         def init tov data():
             X = np.linspace(-0.2, 0.5, num=num_inputs*input_size).reshape(num_inputs, input_size)
             y = np.array([0, 1, 2, 2, 1])
             return X, y
         model = init_toy_model()
         X, y = init_toy_data()
```

#### Forward pass: compute scores

Open the file cs231n/classifiers/neural\_net.py and look at the function two\_layer\_net. This function is very similar to the loss functions you have written for the Softmax exercise in HW0: It takes the data and weights and computes the class scores, the loss, and the gradients on the parameters.

Implement the first part of the forward pass which uses the weights and biases to compute the scores for all inputs.

```
In [85]: from cs231n.classifiers.neural_net import two_layer_net
    scores = two_layer_net(X, model)
    print(scores)
    correct_scores = [[-0.5328368, 0.20031504, 0.93346689],
        [-0.59412164, 0.15498488, 0.9040914 ],
        [-0.67658362, 0.08978957, 0.85616275],
        [-0.77092643, 0.01339997, 0.79772637],
        [-0.89110401, -0.08754544, 0.71601312]]

# the difference should be very small. We get 3e-8
    print('Difference between your scores and correct scores:')
    print(np.sum(np.abs(scores - correct_scores)))

[[-0.5328368    0.20031504    0.93346689]
        [-0.59412164    0.15498488    0.9040914 ]
        [-0.67658362    0.08978957    0.85616275]
        [-0.77092643    0.01339997    0.79772637]
        [-0.89110401    -0.08754544    0.71601312]]
```

#### Forward pass: compute loss

3.848682278081994e-08

In the same function, implement the second part that computes the data and regularizaion loss.

Difference between your scores and correct scores:

```
In [86]: reg = 0.1
loss, _ = two_layer_net(X, model, y, reg)
correct_loss = 1.38191946092

# should be very small, we get 5e-12
print('Difference between your loss and correct loss:')
print(np.sum(np.abs(loss - correct_loss)))

Difference between your loss and correct loss:
4.6769255135359344e-12
```

#### **Backward pass**

Implement the rest of the function. This will compute the gradient of the loss with respect to the variables W1, b1, W2, and b2. Now that you (hopefully!) have a correctly implemented forward pass, you can debug your backward pass using a numeric gradient check:

```
In [87]: from cs231n.gradient_check import eval_numerical_gradient
          # Use numeric gradient checking to check your implementation of the backward pass.
          # If your implementation is correct, the difference between the numeric and
         # analytic gradients should be less than 1e-8 for each of W1, W2, b1, and b2.
         loss, grads = two_layer_net(X, model, y, reg)
         print(X.shape)
          # these should all be less than 1e-8 or so
         for param_name in grads:
             param_grad_num = eval_numerical_gradient(lambda W: two_layer_net(X, model, y, reg)[0], model[param_name], verbose=False)
             temp = grads[param_name]
             print(f"param: {param_name}"
             print(f"my grad: {temp.shape}")
             print(f"answer: {param_grad_num.shape}")
             print('%s max relative error: %e' % (param name, rel error(param grad num, grads[param name])))
             print()
         (5, 4)
         param: W2
         my grad: (10, 3)
         answer: (10, 3)
         W2 max relative error: 9.913918e-10
         param: b2
         mv grad: (3,)
         answer: (3,)
         b2 max relative error: 8.190173e-11
         param: W1
         my grad: (4, 10)
         answer: (4, 10)
         W1 max relative error: 4.426512e-09
         param: b1
         my grad: (10,)
         answer: (10,)
         b1 max relative error: 5.435431e-08
```

#### Train the network

starting iteration 90

Final loss with vanilla SGD: 0.940686

To train the network we will use SGD with Momentum. Last assignment you implemented vanilla SGD. You will now implement the momentum update and the RMSProp update. Open the file classifier\_trainer.py and familiarize yourself with the ClassifierTrainer class. It performs optimization given an arbitrary cost function data, and model. By default it uses vanilla SGD, which we have already implemented for you. First, run the optimization below using Vanilla SGD:

```
In [88]: from cs231n.classifier_trainer import ClassifierTrainer
         model = init toy model()
         trainer = ClassifierTrainer()
         # call the trainer to optimize the loss
          # Notice that we're using sample_batches=False, so we're performing Gradient Descent (no sampled batches of data)
         best_model, loss_history, _, _ = trainer.train(X, y, X, y,
                                                      model, two_layer_net,
                                                      reg=0.001,
                                                      learning_rate=1e-1, momentum=0.0, learning_rate_decay=1,
                                                      update='sgd', sample_batches=False,
                                                      num_epochs=100,
                                                      verbose=False)
         print('Final loss with vanilla SGD: %f' % (loss_history[-1], ))
         starting iteration 0
         starting iteration 10
         starting iteration 20
         starting iteration 30
         starting iteration 40
         starting iteration 50
         starting iteration 60
         starting iteration
         starting iteration 80
```

Now fill in the **momentum update** in the first missing code block inside the train function, and run the same optimization as above but with the momentum update. You should see a much better result in the final obtained loss:

```
In [89]: model = init_toy_model()
         trainer = ClassifierTrainer()
         # call the trainer to optimize the loss
         reg=0.001,
                                               learning_rate=1e-1, momentum=0.9, learning_rate_decay=1,
                                               update='momentum', sample_batches=False,
                                               num_epochs=100,
                                               verbose=False)
         correct_loss = 0.494394
        print('Final loss with momentum SGD: %f. We get: %f' % (loss_history[-1], correct_loss))
        starting iteration 0
        starting iteration 10
        starting iteration 20
         starting iteration 30
         starting iteration 40
         starting iteration 50
        starting iteration 60
        starting iteration 70
        starting iteration 80
         starting iteration 90
        Final loss with momentum SGD: 0.494394. We get: 0.494394
The RMSProp update step is given as follows:
```

```
cache = decay_rate * cache + (1 - decay_rate) * dx**2
x += - learning_rate * dx / np.sqrt(cache + 1e-8)
```

Here, decay\_rate is a hyperparameter and typical values are [0.9, 0.99, 0.999].

Implement the  ${\bf RMSProp}$  update rule inside the  ${\,\tt train}\,$  function and rerun the optimization:

```
In [90]: model = init_toy_model()
         trainer = ClassifierTrainer()
         # call the trainer to optimize the loss
         # Notice that we're using sample_batches=False, so we're performing Gradient Descent (no sampled batches of data)
         best_model, loss_history, _, _ = trainer.train(X, y, X, y,
                                                     model, two_layer_net,
                                                     reg=0.001,
                                                      learning_rate=1e-1, momentum=0.9, learning_rate_decay=1,
                                                     update='rmsprop', sample_batches=False,
                                                     num_epochs=100,
                                                     verbose=False)
         correct loss = 0.439368
         print('Final loss with RMSProp: %f. We get: %f' % (loss_history[-1], correct_loss))
         starting iteration 0
         starting iteration 10
         starting iteration 20
         starting iteration 30
         starting iteration 40
         starting iteration 50
         starting iteration 60
         starting iteration 70
         starting iteration 80
         starting iteration 90
         Final loss with RMSProp: 0.439368. We get: 0.439368
```

# Load the data

Now that you have implemented a two-layer network that passes gradient checks, it's time to load up our favorite CIFAR-10 data so we can use it to train a classifier.

```
In [91]: from cs231n.data_utils import load_CIFAR10
            def get CIFAR10 data(num training=49000, num validation=1000, num test=1000):
                  Load the CIFAR-10 dataset from disk and perform preprocessing to prepare
                  it for the two-layer neural net classifier.
                 # Load the raw CIFAR-10 data
cifar10_dir = 'cs231n/datasets/cifar-10-batches-py'

```

#### Train a network

To train our network we will use SGD with momentum. In addition, we will adjust the learning rate with an exponential learning rate schedule as optimization proceeds; after each epoch, we will reduce the learning rate by multiplying it by a decay rate.

```

## Debug the training

With the default parameters we provided above, you should get a validation accuracy of about 0.37 on the validation set. This isn't very good.

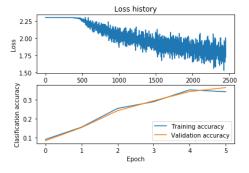

One strategy for getting insight into what's wrong is to plot the loss function and the accuracies on the training and validation sets during optimization.

Another strategy is to visualize the weights that were learned in the first layer of the network. In most neural networks trained on visual data, the first layer weights typically show some visible structure when visualized.

```
In [56]: # Plot the loss function and train / validation accuracies
plt.subplot(2, 1, 1)
plt.plot(loss_history)
plt.title('Loss history')
plt.xlabel('Iteration')
plt.ylabel('Iteration')
plt.ylabel('Loss')

plt.subplot(2, 1, 2)
plt.plot(train_acc)
plt.plot(val_acc)
plt.legend(['Training accuracy', 'Validation accuracy'], loc='lower right')
plt.xlabel('Epoch')
plt.ylabel('Clasification accuracy')
```

Out[56]: Text(0,0.5,'Clasification accuracy')

```
In [57]: from cs231n.vis_utils import visualize_grid

# Visualize the weights of the network

def show_net_weights(model):
    plt.imshow(visualize_grid(model['Wl'].T.reshape(-1, 32, 32, 3), padding=3).astype('uint8'))
    plt.gca().axis('off')
    plt.show()

show_net_weights(model)
```

# **Tune your hyperparameters**

What's wrong?. Looking at the visualizations above, we see that the loss is decreasing more or less linearly, which seems to suggest that the learning rate may be too low. Moreover, there is no gap between the training and validation accuracy, suggesting that the model we used has low capacity, and that we should increase its size. On the other hand, with a very large model we would expect to see more overfitting, which would manifest itself as a very large gap between the training and validation accuracy.

Tuning. Tuning the hyperparameters and developing intuition for how they affect the final performance is a large part of using Neural Networks, so we want you to get a lot of practice. Below, you should experiment with different values of the various hyperparameters, including hidden layer size, learning rate, numer of training epochs, and regularization strength. You might also consider tuning the momentum and learning rate decay parameters, but you should be able to get good performance using the default values.

Approximate results. You should be aim to achieve a classification accuracy of greater than 50% on the validation set. Our best network gets over 56% on the validation set.

Experiment: You goal in this exercise is to get as good of a result on CIFAR-10 as you can, with a fully-connected Neural Network. For every 1% above 56% on the Test set we will award you with one extra bonus point. Feel free implement your own techniques (e.g. PCA to reduce dimensionality, or adding dropout, or adding features to the solver, etc.).

```
In [122]: best_model = None # store the best model into this
         best_val_acc = 0.0
         # TODO: Tune hyperparameters using the validation set. Store your best trained
          # model in best model.
         # To help debug your network, it may help to use visualizations similar to the
          # ones we used above; these visualizations will have significant qualitative
         # differences from the ones we saw above for the poorly tuned network.
          # Tweaking hyperparameters by hand can be fun, but you might find it useful to
          # write code to sweep through possible combinations of hyperparameters
          # automatically like we did on the previous assignment.

show\_net\_weights(best\_model)

# Run on the test set

When you are done experimenting, you should evaluate your final trained network on the test set.

```
In [124]: scores_test = two_layer_net(X_test, best_model)
    print('Test accuracy: ', np.mean(np.argmax(scores_test, axis=1) == y_test))
    Test accuracy: 0.391
In [ ]:
```

#### Modular neural nets

In the previous exercise, we computed the loss and gradient for a two-layer neural network in a single monolithic function. This isn't very difficult for a small two-layer network, but would be tedious and error-prone for larger networks. Ideally we want to build networks using a more modular design so that we can snap together different types of layers and loss functions in order to quickly experiment with different architectures.

In this exercise we will implement this approach, and develop a number of different layer types in isolation that can then be easily plugged together. For each layer we will implement forward and backward functions. The forward function will receive data, weights, and other parameters, and will return both an output and a cache object that stores data needed for the backward pass. The backward function will receive upstream derivatives and the cache object, and will return gradients with respect to the data and all of the weights. This will allow us to write code that looks like this:

```
def two_layer_net(X, W1, b1, W2, b2, reg):
     # Forward pass; compute scores
     s1, fcl_cache = affine_forward(X, W1, b1)
     a1, relu_cache = relu_forward(s1)
     scores, fc2_cache = affine_forward(a1, W2, b2)
     # Loss functions return data loss and gradients on scores
     data_loss, dscores = svm_loss(scores, y)
     # Compute backward pass
     da1, dW2, db2 = affine backward(dscores, fc2 cache)
     ds1 = relu backward(da1, relu cache)
     dX, dW1, db1 = affine_backward(ds1, fc1_cache)
     # A real network would add regularization here
     # Return loss and gradients
     return loss, dW1, db1, dW2, db2

         %autoreload 2
        def rel_error(x, y):
              " returns relative error """
          return np.max(np.abs(x - y) / (np.maximum(1e-8, np.abs(x) + np.abs(y))))
```

## Affine layer: forward

Open the file cs231n/layers.py and implement the affine\_forward function.

Once you are done we will test your can test your implementation by running the following:

Testing affine\_forward function: difference: 9.769848888397517e-10

### Affine layer: backward

Now implement the affine\_backward function. You can test your implementation using numeric gradient checking.

```
In [4]: # Test the affine backward function
         x = np.random.randn(10, 2, 3)
         w = np.random.randn(6, 5)
         b = np.random.randn(5)
         dout = np.random.randn(10, 5)
         dx_num = eval_numerical_gradient_array(lambda x: affine_forward(x, w, b)[0], x, dout)
         dw_num = eval_numerical_gradient_array(lambda w: affine_forward(x, w, b)[0], w, dout)
         db_num = eval_numerical_gradient_array(lambda b: affine_forward(x, w, b)[0], b, dout)
          , cache = affine_forward(x, w, b)
         dx, dw, db = affine_backward(dout, cache)
         # The error should be less than 1e-10
         print('Testing affine_backward function:')
         print('dx error: ', rel_error(dx_num, dx))
print('dw error: ', rel_error(dw_num, dw))
print('db error: ', rel_error(db_num, db))
         dout (10, 5)
         x (10, 2, 3)
         w(6, 5)
         Testing affine backward function:
         dx error: 2.9002938143112204e-10
         dw error: 2.9279415839353796e-11
         db error: 1.6606257785141173e-11
```

### **ReLU layer: forward**

Implement the relu\_forward function and test your implementation by running the following:

```
In [5]: # Test the relu forward function
       x = np.linspace(-0.5, 0.5, num=12).reshape(3, 4)
       out, _ = relu_forward(x)
                           correct_out = np.array([[ 0.,
       # Compare your output with ours. The error should be around 1e-8
       print('Testing relu_forward function:')
       print('difference: ', rel_error(out, correct_out))
      Testing relu_forward function:
```

difference: 4.999999798022158e-08

# ReLU layer: backward

Implement the relu\_backward function and test your implementation using numeric gradient checking:

```
In [6]: x = np.random.randn(10, 10)
        dout = np.random.randn(*x.shape)
        dx_num = eval_numerical_gradient_array(lambda x: relu_forward(x)[0], x, dout)
         , cache = relu_forward(x)
        dx = relu backward(dout, cache)
        # The error should be around 1e-12
        print('Testing relu_backward function:')
        print('dx error: ', rel_error(dx_num, dx))
        Testing relu_backward function:
        dx error: 3.275590221433177e-12
```

## Loss layers: Softmax and SVM

You implemented these loss functions in the last assignment, so we'll give them to you for free here. It's still a good idea to test them to make sure they work correctly.

```
In [7]: num_classes, num_inputs = 10, 50
        x = 0.001 * np.random.randn(num_inputs, num_classes)
        y = np.random.randint(num classes, size=num inputs)
        dx_num = eval_numerical_gradient(lambda x: svm_loss(x, y)[0], x, verbose=False)
        loss, dx = svm_loss(x, y)
        # Test svm_loss function. Loss should be around 9 and dx error should be 1e-9
        print('Testing svm_loss:')
print('loss: ', loss)
        print('dx error: ', rel error(dx num, dx))
        dx_num = eval_numerical_gradient(lambda x: softmax_loss(x, y)[0], x, verbose=False)
        loss, dx = softmax_loss(x, y)
        # Test softmax_loss function. Loss should be 2.3 and dx error should be 1e-8
        print('\nTesting softmax_loss:')
        print('loss: ', loss)
        print('dx error: ', rel_error(dx_num, dx))
        Testing svm loss:
        loss: 8.997770679279384
        dx error: 8.182894472887002e-10
```

# Convolution layer: forward naive

Testing softmax\_loss: loss: 2.3023626383992823 dx error: 8.380339587422198e-09

We are now ready to implement the forward pass for a convolutional layer. Implement the function conv\_forward\_naive in the file cs231n/layers.py .

You don't have to worry too much about efficiency at this point; just write the code in whatever way you find most clear.

You can test your implementation by running the following:

```
In [8]: x_shape = (2, 3, 4, 4)
w_shape = (3, 3, 4, 4)
         x = np.linspace(-0.1, 0.5, num=np.prod(x_shape)).reshape(x_shape)
         w = np.linspace(-0.2, 0.3, num=np.prod(w_shape)).reshape(w_shape)
         b = np.linspace(-0.1, 0.2, num=3)
         conv_param = {'stride': 2, 'pad': 1}
         [[ 0.21027089, 0.21661097], [ 0.22847626, 0.23004637]],
                                      [[ 0.50813986, 0.54309974],
                                     [ 0.64082444, 0.67101435]]],
[[[-0.98053589, -1.03143541],
                                        [-1.19128892, -1.24695841]],
                                      [[ 0.69108355, 0.66880383], [ 0.59480972, 0.56776003]],
                                       [[ 2.36270298, 2.36904306],
                                        [ 2.38090835, 2.38247847]]]]])
          # Compare your output to ours; difference should be around 1e-8
         print('Testing conv_forward_naive')
print('difference: ', rel_error(out, correct_out))
         Testing conv_forward_naive
```

# Aside: Image processing via convolutions

difference: 2.212147649671884e-08

As fun way to both check your implementation and gain a better understanding of the type of operation that convolutional layers can perform, we will set up an input containing two images and manually set up filters that perform common image processing operations (grayscale conversion and edge detection). The convolution forward pass will apply these operations to each of the input images. We can then visualize the results as a sanity check.

```
In [9]: from scipy.misc import imread, imresize
         kitten, puppy = imread('kitten.jpg'), imread('puppy.jpg')
         # kitten is wide, and puppy is already square
d = kitten.shape[1] - kitten.shape[0]
         kitten_cropped = kitten[:, d//2:-d//2, :]
         img_size = 200
                          # Make this smaller if it runs too slow
        x = np.zeros((2, 3, img_size, img_size))
x[0, :, :, :] = imresize(puppy, (img_size, img_size)).transpose((2, 0, 1))
         x[1,:,:,:] = imresize(kitten_cropped, (img_size, img_size)).transpose((2, 0, 1))
         # Set up a convolutional weights holding 2 filters, each 3x3
         w = np.zeros((2, 3, 3, 3))
         # The first filter converts the image to gravscale.
         # Set up the red, green, and blue channels of the filter.
         w[0, 0, :, :] = [[0, 0, 0], [0, 0.3, 0], [0, 0, 0]]
         w[0, 1, :, :] = [[0, 0, 0], [0, 0.6, 0], [0, 0, 0]]
         w[0, 2, :, :] = [[0, 0, 0], [0, 0.1, 0], [0, 0, 0]]
         # Second filter detects horizontal edges in the blue channel.
         w[1, 2, :, :] = [[1, 2, 1], [0, 0, 0], [-1, -2, -1]]
         # Vector of biases. We don't need any bias for the grayscale
         # filter, but for the edge detection filter we want to add 128
         # to each output so that nothing is negative.
         b = np.array([0, 128])
         # Compute the result of convolving each input in x with each filter in w,
         # offsetting by b, and storing the results in out.
         out, _ = conv_forward_naive(x, w, b, {'stride': 1, 'pad': 1})
         def imshow_noax(img, normalize=True):
                 Tiny helper to show images as uint8 and remove axis labels """
             if normalize:
                  img_max, img_min = np.max(img), np.min(img)
img = 255.0 * (img - img_min) / (img_max - img_min)
             plt.imshow(img.astype('uint8'))
             plt.gca().axis('off')
         \# Show the original images and the results of the conv operation
         plt.subplot(2, 3, 1)
         imshow noax(puppy, normalize=False)
         plt.title('Original image')
         plt.subplot(2, 3, 2)

dw error: 5.588793674786507e-10
           db error: 8.541292449471228e-11
```

# Max pooling layer: forward naive

The last layer we need for a basic convolutional neural network is the max pooling layer. First implement the forward pass in the function max\_pool\_forward\_naive in the file cs231n/layers.py.

```
In [11]: x_{shape} = (2, 3, 4, 4)
          x = np.linspace(-0.3, 0.4, num=np.prod(x_shape)).reshape(x_shape)
pool_param = {'pool_width': 2, 'pool_height': 2, 'stride': 2}
          out, _ = max_pool_forward_naive(x, pool_param)
          correct_out = np.array([[[[-0.26315789, -0.24842105],
                                       [-0.20421053, -0.18947368]],
                                      [[-0.14526316, -0.13052632],
                                        [-0.08631579, -0.07157895]],
                                      [[-0.02736842, -0.01263158],
[ 0.03157895, 0.04631579]]],
                                     [[[ 0.09052632, 0.10526316],
                                        [ 0.14947368, 0.16421053]],
                                      [[ 0.20842105, 0.22315789],
                                       [ 0.26736842, 0.28210526]],
                                      [[ 0.32631579, 0.34105263], [ 0.38526316, 0.4 ]]
           # Compare your output with ours. Difference should be around 1e-8.
          print('Testing max_pool_forward_naive function:')
          print('difference: ', rel error(out, correct out))
          [[[-0.26315789 -0.24842105]
             [-0.20421053 -0.18947368]]
            [[-0.14526316 -0.13052632]
              [-0.08631579 -0.07157895]]
            [[-0.02736842 -0.01263158]
             [ 0.03157895  0.04631579]]]
           [[[ 0.09052632  0.10526316]
              [ 0.14947368  0.16421053]]
            [[ 0.20842105  0.22315789]
             [ 0.26736842  0.28210526]]
            [[ 0.32631579  0.34105263]
             [ 0.38526316  0.4
                                      1111
          Testing max_pool_forward_naive function:
          difference: 4.1666665157267834e-08
```

# Max pooling layer: backward naive

Implement the backward pass for a max pooling layer in the function max\_pool\_backward\_naive in the file cs231n/layers.py . As always we check the correctness of the backward pass using numerical gradient checking.

```
In [12]: x = np.random.randn(3, 2, 8, 8)
dout = np.random.randn(3, 2, 4, 4)
pool_param = {'pool_height': 2, 'pool_width': 2, 'stride': 2}

dx_num = eval_numerical_gradient_array(lambda x: max_pool_forward_naive(x, pool_param)[0], x, dout)

out, cache = max_pool_forward_naive(x, pool_param)
dx = max_pool_backward_naive(dout, cache)

# Your error should be around le-12
print('Testing max_pool_backward_naive function:')
print('dx error: ', rel_error(dx, dx_num))
```

Testing max\_pool\_backward\_naive function:
dx error: 3.2756338833305833e-12

### **Fast layers**

Making convolution and pooling layers fast can be challenging. To spare you the pain, we've provided fast implementations of the forward and backward passes for convolution and pooling layers in the file cs231n/fast layers.py.

The fast convolution implementation depends on a Cython extension; to compile it you need to run the following from the cs231n directory:

```
python setup.py build_ext --inplace
```

Naive: 13.820877s Fast: 0.017050s Speedup: 810.607302x

The API for the fast versions of the convolution and pooling layers is exactly the same as the naive versions that you implemented above: the forward pass receives data, weights, and parameters and produces outputs and a cache object; the backward pass receives upstream derivatives and the cache object and produces gradients with respect to the data and weights.

**NOTE:** The fast implementation for pooling will only perform optimally if the pooling regions are non-overlapping and tile the input. If these conditions are not met then the fast pooling implementation will not be much faster than the naive implementation.

You can compare the performance of the naive and fast versions of these layers by running the following:

```
In [13]: from cs231n.fast_layers import conv_forward_fast, conv_backward_fast
             from time import time
            x = np.random.randn(100, 3, 31, 31)
            w = np.random.randn(25, 3, 3, 3)

# Sandwich layers

db error: 2.580480876527029e-11

In [15]: from cs231n.layer\_utils import conv\_relu pool forward, conv\_relu pool backward

There are a couple common layer "sandwiches" that frequently appear in ConvNets. For example convolutional layers are frequently followed by ReLU and pooling, and affine layers are frequently followed by ReLU. To make it more convenient to use these common patterns, we have defined several convenience layers in the file cs231n/layer\_utils.py . Lets grad-check them to make sure that they work correctly:

```
x = np.random.randn(2, 3, 16, 16)
           w = np.random.randn(3, 3, 3, 3)
           b = np.random.randn(3,)
           dout = np.random.randn(2, 3, 8, 8)
          conv_param = {'stride': 1, 'pad': 1}
pool_param = {'pool_height': 2, 'pool_width': 2, 'stride': 2}
           out, cache = conv_relu_pool_forward(x, w, b, conv_param, pool_param)
           dx, dw, db = conv_relu_pool_backward(dout, cache)
            dx\_num = eval\_numerical\_gradient\_array(lambda x: conv\_relu\_pool\_forward(x, w, b, conv\_param, pool\_param)[0], x, dout) 
           dw_num = eval_numerical_gradient_array(lambda w: conv_relu_pool_forward(x, w, b, conv_param, pool_param)[0], w, dout)
           db num = eval numerical gradient array(lambda b: conv relu pool forward(x, w, b, conv param, pool param)[0], b, dout)
           print('Testing conv_relu_pool_forward:')
          print('dx error: ', rel_error(dx_num, dx))
print('dw error: ', rel_error(dw_num, dw))
print('db error: ', rel_error(db_num, db))

#### Train a ConvNet!

We now have a generic solver and a bunch of modularized layers. It's time to put it all together, and train a ConvNet to recognize the classes in CIFAR-10. In this notebook we will walk you through training a simple two-layer ConvNet and then set you free to build the best net that you can to perform well on CIFAR-10.

Open up the file cs231n/classifiers/convnet.py; you will see that the two\_layer\_convnet function computes the loss and gradients for a two-layer ConvNet. Note that this function uses the "sandwich" layers defined in cs231n/layer\_utils.py.

```
In [1]: # As usual, a bit of setup
        import numpy as np
        import matplotlib.pyplot as plt
        from cs231n.classifier_trainer import ClassifierTrainer
        from cs231n.gradient_check import eval_numerical_gradient
        from cs231n.classifiers.convnet import *
         %matplotlib inline
        plt.rcParams['figure.figsize'] = (10.0, 8.0) # set default size of plots
        plt.rcParams['image.interpolation'] = 'nearest'
        plt.rcParams['image.cmap'] = 'gray'
         # for auto-reloading external modules
         # see http://stackoverflow.com/questions/1907993/autoreload-of-modules-in-ipython
         %load_ext autoreload
         %autoreload 2
        def rel_error(x, y):
    """ returns relative error """
          return np.max(np.abs(x - y) / (np.maximum(1e-8, np.abs(x) + np.abs(y))))
```

```
In [2]: from cs231n.data utils import load CIFAR10
         def get CIFAR10 data(num_training=49000, num_validation=1000, num_test=1000):
              Load the CIFAR-10 dataset from disk and perform preprocessing to prepare
              it for the two-layer neural net classifier. These are the same steps as
              we used for the SVM, but condensed to a single function.
              # Load the raw CIFAR-10 data
              cifar10_dir = 'cs231n/datasets/cifar-10-batches-py'

              mean_image = np.mean(X_train, axis=0)
              X_train -= mean_image
              X_val -= mean_image
             X_test -= mean_image
              # Transpose so that channels come first
              X_train = X_train.transpose(0, 3, 1, 2).copy()
              X_{val} = X_{val.transpose(0, 3, 1, 2).copy()}
              x_test = X_test.transpose(0, 3, 1, 2).copy()
              return X_train, y_train, X_val, y_val, X_test, y_test
         # Invoke the above function to get our data.
         X_train, y_train, X_val, y_val, X_test, y_test = get_CIFAR10_data()
         print('Train data shape: ', X_train.shape)
print('Train labels shape: ', y_train.shape)
         print('Validation data shape: ', X_val.shape)
print('Validation labels shape: ', y_val.shape)
         print('Test data shape: ', X_test.shape)
print('Test labels shape: ', y_test.shape)
         Train data shape: (49000, 3, 32, 32)
         Train labels shape: (49000,)
         Validation data shape: (1000, 3, 32, 32)
         Validation labels shape: (1000,)
Test data shape: (1000, 32, 32, 3)
```

# Sanity check loss

Test labels shape: (1000,)

After you build a new network, one of the first things you should do is sanity check the loss. When we use the softmax loss, we expect the loss for random weights (and no regularization) to be about log(C) for C classes. When we add regularization this should go up.

```
In [3]: model = init_two_layer_convnet()
        X = np.random.randn(100, 3, 32, 32)
        y = np.random.randint(10, size=100)
        loss, = two layer convnet(X, model, y, reg=0)
        # Sanity check: Loss should be about log(10) = 2.3026
        print('Sanity check loss (no regularization): ', loss)
        # Sanity check: Loss should go up when you add regularization
                = two_layer_convnet(X, model, y, reg=1)
        print('Sanity check loss (with regularization): ', loss)
        dout (100, 10)
        x (100, 32, 16, 16)
        w (8192, 10)
        Sanity check loss (no regularization): 2.302680787589569
        dout (100, 10)
        x (100, 32, 16, 16)
        w (8192, 10)
```

#### **Gradient check**

Sanity check loss (with regularization): 2.344563384742511

After the loss looks reasonable, you should always use numeric gradient checking to make sure that your backward pass is correct. When you use numeric gradient checking you should use a small amount of artifical data and a small number of neurons at each layer.

```
In [5]:    num_inputs = 2
    input_shape = (3, 16, 16)
    reg = 0.0
    num_classes = 10
    X = np.random.randn(num_inputs, *input_shape)
    y = np.random.randint(num_classes, size=num_inputs)

model = init_two_layer_convnet(num_filters=3, filter_size=3, input_shape=input_shape)
    loss, grads = two_layer_convnet(X, model, y)
    for param_name in sorted(grads):
        f = lambda _: two_layer_convnet(X, model, y)[0]
        param_grad_num = eval_numerical_gradient(f, model[param_name], verbose=False, h=le-6)
        e = rel_error(param_grad_num, grads[param_name])
        print('%s max relative error: %e' % (param_name, rel_error(param_grad_num, grads[param_name]))))

W1 max relative error: 1.462154e-06
    W2 max relative error: 1.090814e-05
    b1 max relative error: 1.78371le-08
```

# Overfit small data

b2 max relative error: 2.063144e-09

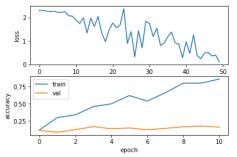

A nice trick is to train your model with just a few training samples. You should be able to overfit small datasets, which will result in very high training accuracy and comparatively low validation accuracy.

```
In [6]: # Use a two-layer ConvNet to overfit 50 training examples.
        model = init_two_layer_convnet()
        trainer = ClassifierTrainer()
        best_model, loss_history, train_acc_history, val_acc_history = trainer.train(
                  X_train[:50], y_train[:50], X_val, y_val, model, two_layer_convnet,
                  reg=0.001, momentum=0.9, learning_rate=0.0001, batch_size=10, num_epochs=10,
                  verbose=True)
        starting iteration 0

        finished optimization. best validation accuracy: 0.177000
```

Plotting the loss, training accuracy, and validation accuracy should show clear overfitting:

```
In [7]: plt.subplot(2, 1, 1)
    plt.plot(loss_history)
    plt.xlabel('iteration')
    plt.ylabel('loss')

    plt.subplot(2, 1, 2)
    plt.plot(train_acc_history)
    plt.plot(val_acc_history)
    plt.legend(['train', 'val'], loc='upper left')
    plt.xlabel('epoch')
    plt.ylabel('accuracy')
    plt.show()
```

# Train the net

Once the above works, training the net is the next thing to try. You can set the acc\_frequency parameter to change the frequency at which the training and validation set accuracies are tested. If your parameters are set properly, you should see the training and validation accuracy start to improve within a hundred iterations, and you should be able to train a reasonable model with just one epoch.

Using the parameters below you should be able to get around 50% accuracy on the validation set.

# Visualize weights

We can visualize the convolutional weights from the first layer. If everything worked properly, these will usually be edges and blobs of various colors and orientations.

```
In [9]: from cs231n.vis_utils import visualize_grid

grid = visualize_grid(best_model['Wl'].transpose(0, 2, 3, 1))
plt.imshow(grid.astype('uint8'))
```

Out[9]: <matplotlib.image.AxesImage at 0x1041d8080>

```
